Chloride-based chemical doping yields low-contact-resistance molybdenum disulfide field-effect transistors

SRC- and SEMATECH-supported Purdue research presented at VLSI

At the 2014 Symposium on VLSI Technology and Circuits in Honolulu, Hawaii (9–13 June), a team at Purdue University, SEMATECH of Albany, NY, USA (the international research consortium of semiconductor device, equipment, and materials manufacturers) and the State University of New York (SUNY) College of Nanoscale Science and Engineering (CNSE, where SEMATECH is based) has presented a chemical doping technique that has reduced contact resistance ($R_c$) by 10-fold and specific contact resistivity ($\rho_c$) by 100-fold to enable the demonstration of high-performance molybdenum disulfide ($\text{MoS}_2$) field-effect transistors (FETs).

The paper ‘High-Performance MoS$_2$ Field-Effect Transistors Enabled by Chloride Doping: Record Low Contact Resistance (0.5kΩ·μm) and Record High Drain Current (460μA/μm)’ was authored by Purdue doctoral students Lingming Yang, Yuchen Du, Han Liu and Heng Wu; SEMATECH researchers Kausik Majumdar, Py Hung, Robert Tieckelmann and Chris Hobbs; CNSE researcher Michael Hatzistergos; Intel’s Wilman Tsai; and Purdue professor of electrical and computer engineering Peide Ye.

The research is said to be an important milestone for the realization of ultra-scaled low-power two-dimensional (2D) MoS$_2$ FETs and the advancement of photonic and electronic devices based on transition metal dichalcogenide (TMD) materials such as solar cells, photono-transistors and low-power logic FETs. The work is supported by SEMATECH and Semiconductor Research Corporation (SRC) of Research Triangle Park, NC, USA (the university-research consortium for semiconductors and related technologies).

As part of the research, the team leveraged MoS$_2$, which has been studied closely by the semiconductor industry in recent years due to its potential applications in electrical and optical devices. However, high contact resistance significantly limits the device performance of MoS$_2$ FETs. One method for resolving this is to dope the MoS$_2$ film, but doping the atomically thin film is non-trivial and requires a simple and reliable process technique.

The technique used by the research team provides an effective and straightforward way for ‘molecular layer doping’ of the MoS$_2$ film with the chloride-based chemical doping reagent 1,2 dichloroethane (DCE) to significantly reduce the contact resistance.

‘Due to recent advances such as the research being presented at the VLSI Symposium, 2D materials are gaining a lot of attention in the semiconductor industry,’ says Satyavolu Papa Rao, SEMATECH’s director of Process Technology. ‘The collaborative effort among world-class researchers and engineers from this team is a prime example of how consortium-university-industry partnerships further enable the development of cutting-edge process techniques,’ he adds.

‘Improved contacts are always desirable for all electronic and optical devices,’ notes Kwok Ng, senior director of Device Sciences at SRC. ‘The doping technique presented by this research team provides a valid way to achieve low contact resistance for MoS$_2$ as well as other TMD materials.’
